## Abstract

**Background/Aims:** Obesity is a major global health issue, exacerbated by reduced physical activity due to technological advancements. Bariatric surgery is the most effective treatment for significant weight loss. This study examines 2-month post-operative changes in anthropometric parameters, muscle strength, and regional fat reduction in female patients.

**Materials and Methods:** In this observational prospective study, anthropometric measurements were collected from female patients who underwent laparoscopic sleeve gastrectomy between October 2022 and March 2023. Data were recorded pre-operatively and at the 1st and 2nd months post-surgery.

**Results:** A significant reduction in skinfold thickness, indicative of fat mass reduction, was observed, alongside a marked improvement in grip strength within the 8-week post-operative period.

**Conclusion:** This study is notable for being the first to comprehensively evaluate short-term changes in skinfold thickness following bariatric surgery. Additionally, it is pioneering in its application of the pinch strength test alongside the hand grip strength test in this context.

## 1. Introduction

Obesity is a major global health issue, driven partly by reduced physical activity due to technological advancements like automation and computerization. It imposes significant financial burdens on healthcare systems.<sup>1</sup> According to WHO's 2016 data, 1.9 billion adults are overweight, and 650 million (13%) are obese, with obesity rates of 39% in men and 15% in women.<sup>2,3</sup> In Türkiye, Ministry of Health data show obesity rates of 20.9% in women, 13.7% in men, and 17% overall.<sup>4</sup>

Obesity increases the risk of insulin resistance, type II diabetes, hypertension, dyslipidemia, sleep apnea, cardiovascular diseases,<sup>5,6</sup> and cancer.<sup>7</sup> It affects the sympathetic nervous system,<sup>8,9</sup> contributes to musculoskeletal issues, gallbladder disease, non-alcoholic fatty liver disease, pulmonary dysfunction,<sup>10</sup> and is linked to a sedentary lifestyle, reduced cardiopulmonary fitness,<sup>11</sup> and lower life expectancy.<sup>12</sup>

Bariatric surgery is an effective treatment for significant, long-term weight loss and preventing obesity-related complications.<sup>13</sup> It provides substantial benefits with minimal complications for most morbidly obese patients.<sup>14</sup> Typically considered after the failure of non-surgical methods like diet, exercise, and medications, it also improves obesity-related comorbidities and modifies fasting and satiety patterns.<sup>15</sup>

Laparoscopic sleeve gastrectomy (LSG) is a widely accepted bariatric procedure involving the removal of about two-thirds of the stomach, leaving a tube-shaped stomach.<sup>16</sup> The incision starts 4-5 cm from the pylorus and extends to the angle of His. Patients typically lose up to 20% of their total body weight within the first year.<sup>16</sup>

1  
2  
3 Skinfold thickness is a simple, cost-effective method to estimate body fat, assuming  
4 subcutaneous fat reflects total body fat proportion. Measurements using a caliper provide an  
5 alternative to weight and height-based metrics.<sup>17,18</sup>  
6  
7  
8  
9

10  
11 Postoperative follow-up is essential for reducing weight regain and ensuring patient  
12 safety after bariatric surgery. A primary goal is to reduce body fat while preserving lean body  
13 mass (LBM), particularly body cell mass—a critical LBM subset vital for maintaining  
14 metabolic and physical functions.<sup>19</sup>  
15  
16  
17  
18  
19

20  
21 Post-bariatric monitoring of weight, muscle and fat loss, muscle strength, and body fat  
22 distribution is crucial for surgeons and dietitians. This study aims to examine short-term (2-  
23 month) changes in anthropometric parameters among female patients, assess weight loss  
24 effects on muscle strength, and quantify regional fat reduction post-surgery.  
25  
26

## 30 **2. Materials and Methods**

### 31 **2.1. Study Design**

32  
33  
34 This prospective cross-sectional study included 26 female patients who underwent LSG  
35 at Kırşehir Training and Research Hospital between October 2022 and March 2023. These  
36 patients, eligible for bariatric surgery due to unsuccessful weight loss despite lifestyle and  
37 pharmacological interventions, had their demographic and anthropometric data collected  
38 before the procedure.  
39  
40  
41  
42  
43  
44  
45  
46  
47

48  
49 All patients followed a standardized post-operative nutritional plan, starting with a 15-  
50 day liquid diet, progressing to pureed, and eventually solid foods, with a recommended daily  
51 intake of 400-500 kcal to ensure weight loss. Anthropometric assessments were performed at  
52 baseline and during the first and second post-operative months. Two patients missing follow-  
53 up data were excluded from the final analysis. The study received ethical approval from the  
54  
55

4  
5 09/97). Informed consent was obtained from all participants.  
6  
7

## 8 **2.2. Anthropometric Measurements**

9

10  
11 The data collection process was conducted 1–3 days before surgery and during the 1st  
12 and 2nd post-operative months. Demographic information was collected via a structured  
13 questionnaire, and 11 anthropometric measurements were taken from 9 anatomical sites using  
14 a skinfold caliper, including Vertical and Horizontal Abdominal Skinfold Thickness (ASFv,  
15 ASFh), Triceps (TSF), Biceps (BSF), Chest (CSF), Vertical and Horizontal Midaxillary  
16 Skinfold Thickness (MSFv, MSFh), Subscapular (SSSF), Thigh (TSF), Suprailiac (SISF), and  
17 Medial Calf (MCSF). Pinch strength measurements—Tip Pinch (TP), Key Pinch (KP), and  
18 Palmar Pinch (PP)—and circumferential measurements—Waist (WC), Hip (HC), and Neck  
19 Circumference (NC)—were recorded, alongside Hand Grip Strength (HGS), totaling 18  
20 measurement points.  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34

35 Pinch strength was measured using a digital pinch meter with participants positioned as  
36 follows: shoulders adducted, elbows flexed at 90°, forearms in neutral, and wrists at 0–30°  
37 dorsiflexion and 0–15° ulnar deviation. The highest recorded value for each hand was used for  
38 analysis.<sup>20</sup> Circumferential measurements were taken in centimeters with a non-stretchable  
39 tape. WC was measured at the umbilicus, HC at the widest hip part, and NC at the midpoint  
40 between the middle cervical spine and anterior neck. The waist-to-hip ratio (WHR) and waist-  
41 to-height ratio (WHtR) were calculated from these measurements.  
42  
43  
44  
45  
46  
47  
48  
49  
50

51 HGS was assessed using a digital dynamometer with the participant standing, and  
52 measurements were taken from the dominant hand. Central obesity indices derived from WC,  
53 such as the conicity index (CI) and a-body shape index (ABSI), were included. CI incorporates  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 WC, height, and weight to analyze fat distribution, while ABSI, based on WC, is largely  
4 independent of height, weight, and body mass index (BMI).<sup>21</sup>  
5  
6

7  
8 CI was calculated as follows:  
9

$$10 \quad CI = \frac{WC \text{ (m)}}{0.109 \times \sqrt{\text{weight (kg)} / \text{height (m)}}}$$

11  
12  
13  
14  
15  
16  
17 ABSI was calculated as follows:  
18

$$19 \quad ABSI = \frac{WC \text{ (m)}}{BMI^{\frac{2}{3}} \times \text{height (m)}^{\frac{1}{2}}}$$

20  
21  
22  
23  
24  
25 All measurements were performed twice by the same person in the research group, and the  
26 highest values measured for grip strength and pinch forces were recorded.  
27  
28

### 29 30 **2.3. Statistical analysis** 31

32  
33 Statistical analysis of the study data was performed using SPSS version 29.0 software  
34 for Windows (IBM SPSS Statistics for Windows, Version 29.0. Armonk, NY: IBM Corp.,  
35 USA) The Shapiro–Wilk test were used to examine the normality of the quantitative  
36 continuously variable. Descriptive statistics were presented using mean±SD,  
37 median(minimum-maximum) where appropriate. Differences in the Anthropometric  
38 Parameters readings in were compared using Repeated Measures Analysis of variance (if  
39 normality and sphericity assumptions were satisfied); otherwise, the Friedman test was used.  
40 Pairwise comparisons were using Bonferroni multiple comparison test (if assumptions were  
41 satisfied) otherwise the Wilcoxon signed-rank test was used. A value of p <0.05 was accepted  
42 as statistically significant.

### 3. Results

Measurements were conducted preoperatively and at one and two months postoperatively, assessing ASFv, ASFh, TSF, BSF, CSF, MSFv, MSFh, SSSF, TSF, SISF, MCSF, TP, KP, PP, HGS, WC, HC, and NC. Descriptive statistics and intergroup comparisons are presented (Table 1). These statistics and comparisons visualized (Figure 1). Significant improvements were observed postoperatively across most parameters compared to baseline, reflecting the positive impact of the surgical intervention.

Significant reductions were noted in ASFv, ASFh, TSF, BSF, CSF, MSFv, MSFh, SSSF, TSF, MCSF, SISF, WC, HC, NC, WHtR, WHR, HGS, PP, and KP ( $p < 0.05$ ) (Figure 1). However, non-significant changes were found for ASFv and HGS during the 2nd postoperative period ( $p = 0.112$ ,  $p = 1.000$ , respectively). KP showed significance only in the 1st postoperative period, while WHR and PP showed changes only in the 2nd postoperative period (Table 1). TP remained non-significant across all time points ( $p = 0.237$ ).

Comparisons of ABSI and CI, limited to preoperative and 2nd postoperative measurements, revealed a significant reduction in CI ( $p < 0.05$ ), while ABSI showed no significant change. This indicates a stronger response to intervention in CI than ABSI (Table 2).

#### 9 **4. Discussion**

10  
11  
12 In the first 8 weeks post-surgery, significant reductions in body weight and skinfold  
13 thickness, indicative of fat mass loss, were observed alongside notable improvements in grip  
14 strength. To our knowledge, this is the first study from Türkiye to track anthropometric  
15 measurements after surgery and the first in the literature to comprehensively investigate  
16 reductions in skinfold thickness and regional fat tissue.  
17  
18  
19  
20  
21  
22

23  
24 While body weight and BMI are common obesity indicators, they fail to distinguish  
25 between fat and muscle mass.<sup>22</sup> Alternative measures such as skinfold thickness, WC, HC,  
26 WHR, and WHtR provide more precise insights into fat distribution. Skinfold measurements  
27 are widely used due to their affordability and simplicity, while combining them with WC and  
28 HC improves predictive accuracy. Garcia et al. emphasized that combining skinfolds with  
29 circumferences yields more accurate body fat estimates.<sup>23</sup>  
30  
31  
32  
33  
34  
35  
36  
37  
38

39 Sans et al. reported a 25% reduction in WC and HC and a 50% reduction in triceps  
40 skinfold thickness (TSF) after one year in 103 morbidly obese women undergoing Roux-en-Y  
41 Gastric Bypass (RYGP).<sup>24</sup> Similarly, Strauss et al. observed a 30% reduction in the sum of  
42 skinfold thicknesses at four sites in 17 patients undergoing gastric banding over a 2.5-year  
43 follow-up.<sup>25</sup>  
44  
45  
46  
47  
48  
49  
50

51 Our study provides the most comprehensive analysis of skinfold thickness reductions  
52 in LSG patients, assessing 9 sites and 11 measurements. Significant reductions in all skinfold  
53 thicknesses in the short-term postoperative period confirm the efficacy of LSG in reducing  
54 adiposity.  
55  
56  
57  
58  
59  
60

1  
2  
3 Additionally, we evaluated static muscle strength changes, focusing on grip strength  
4 after bariatric surgery. Hand and pinch grip strength, non-invasive and cost-effective indicators  
5 of upper extremity muscle function, are increasingly recognized as predictors of mortality and  
6 morbidity in clinical settings.<sup>19</sup>  
7  
8  
9  
10

11  
12  
13 Previous studies have reported inconsistent results regarding changes in muscle strength  
14 after bariatric surgery. Alba et al. noted a decline in dynamic muscle strength 6–12 months  
15 post-RYGP, while Cole et al. and Colar et al. found no significant changes in HGS at 6 and 12  
16 months postoperatively.<sup>26-28</sup> Similarly, Ibacache et al. observed reduced HGS at 1 and 3 months  
17 post-LSG, but other studies reported no significant changes in muscle strength.<sup>19,29-32</sup>  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27

28 In contrast, our study demonstrated a significant increase in HGS during the first and  
29 second postoperative months (Table 1). Additionally, we are the first to evaluate pinch strength  
30 in LSG patients, revealing significant improvements in KP and PP strengths between pre-and  
31 postoperative measurements (Table 1). These results highlight the positive impact of LSG on  
32 muscle strength in the early postoperative period, differing from prior studies.  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42

43 Anthropometric measurements such as WC, HC, NC, WHR, and WHtR are widely used  
44 for evaluating obesity in bariatric surgery. Our results align with those reported by Ahuja,  
45 Shirazi, Carvajal, Shah, Hosseini-Esfahani, and Sans. For example, Talalaj et al. documented  
46 reductions of 22.1% in WC, 18.4% in HC, and 4.2% in WHR 12 months post-LSG. Shirazi et  
47 al. observed reductions of 17.1% in WC, 17.3% in HC, and 17.5% in WHtR, while Carvajal et  
48 al. reported decreases of 20% in WC, 14% in HC, and 10% in NC at 6 months.<sup>23,24</sup>  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 In our study, reductions of 12.5% in WC, 10.1% in HC, 10% in NC, 2.6% in WHR, and  
4  
5 12.5% in WHtR were observed within 2 months, demonstrating rapid postoperative changes  
6  
7 and the efficacy of LSG in reducing obesity-related parameters.  
8  
9

10  
11  
12  
13  
14 CI, a reliable indicator of fat distribution, is cost-effective and effective in detecting  
15  
16 abdominal obesity.<sup>33</sup> Shirazi et al. reported a 30% reduction in CI 12 months post-LSG.<sup>3</sup> In our  
17  
18 study, a 4% reduction was observed within 2 months, underscoring its utility in early  
19  
20 postoperative assessments.  
21  
22

23  
24  
25  
26  
27 ABSI, which adjusts WC for BMI and height, offers a refined measure of central  
28  
29 adiposity and is an independent predictor of mortality. Huang et al. found significant pre- and  
30  
31 postoperative differences in ABSI in gastric bypass and sleeve gastrectomy patients,  
32  
33 highlighting its potential in bariatric outcomes.<sup>34</sup>  
34  
35

## 36 37 38 39 **5. Conclusions**

40  
41  
42 In conclusion, obesity is a chronic, multifactorial condition associated with numerous  
43  
44 comorbidities and a high risk of recurrence despite treatment. LSG is an effective surgical  
45  
46 option, but long-term success requires ongoing postoperative management, including lifestyle  
47  
48 modifications in diet and physical activity.  
49  
50

51  
52  
53  
54  
55 Anthropometric assessments, such as skinfold thickness, circumferential measurements,  
56  
57 WHtR, and CI, are essential tools for monitoring progress after LSG, providing a  
58  
59  
60

1  
2  
3 comprehensive evaluation of nutritional and metabolic status and helping reduce the risk of  
4  
5 weight regain.  
6  
7  
8  
9

10  
11 Our study is the first to comprehensively analyze short-term postoperative changes in skinfold  
12  
13 thickness and integrate pinch strength testing with HGS assessments, offering a detailed  
14  
15 evaluation of muscle function and body composition in post-surgical recovery.
